

M50195P

DIGITAL ECHO

DESCRIPTION

The M50195P is a digital ECHO IC fabricated with silicon-gate CMOS technology.

The M50195P converts an input analog signal to a digital signal and writes it in a memory IC. After a delay it reads out the digital signal from the memory IC and then converts to an analog signal again.

Lower noise and distortion delay signal is obtained by M50195P than by BBD. An A-D, D-A converter block formed of ADM (Adaptive Delta Modulation) circuit can produce a low cost delay system.

FEATURES

- Low noise (-90dBV typ)
Low distortion (0.5% typ)
- 3mode delay time (100, 150, 200msec)

APPLICATION

Karaoke, Radio cassette tape recorder, Video-disc player, Electronic instrument

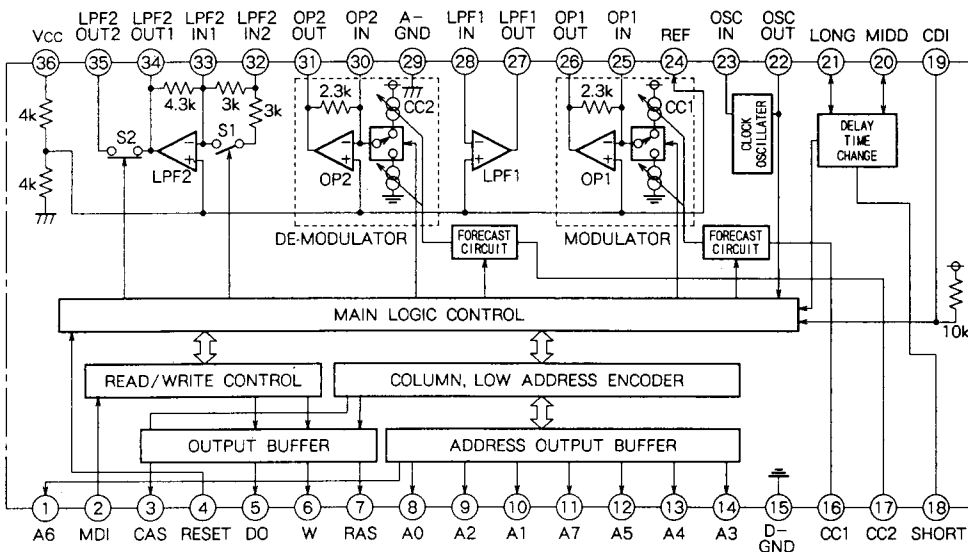

RECOMMENDED OPERATING CONDITIONS

- Supply voltage range.....4.0~5.5V
- Rated supply voltage.....5V

IN FUNCTIONS

Function	Symbol	Function outline
Reference voltage generator	REF	Generates reference voltage of analog circuit (1/2Vcc)
Low pass filter	LPF1, LPF2	Cuts the unnecessary high frequency noise
Adaptive delta modulator	OP1, CC1	Converts analog signal to digital signal
Adaptive delta demodulator	OP2, CC2	Converts digital signal to analog signal
Forecast circuit		Makes the ADM operate the best suited then improves S/N ratio and distortion
Clock generator circuit		Generates the master clock typical frequency f _{clk} = 4MHz
Change to delay time switch		3mode delay time can be selected (SHORT = 100msec, MIDD = 150msec, LONG = 200msec)
Change to gain and frequency characteristic switch	S1	Turns on at SHORT mode, and increase gain 6dB than MIDD or LONG mode operation
Change to feedback value	S2	Turns on at SHORT or MIDD mode, and decreases the feedback gain
Main control logic		Controls ADM circuits, delay time and memory IC
Read/write control		Controls reading or writing to the memory IC
Row column address encoder		Selects the address of the memory IC
Output buffer		Drives the memory IC
Address output buffer
